The CEO of the Superstore wants to know why customers are returning their orders and how can we reduce it. There are charts and graphs made to depict which product categories, geographic regions, times of the year, and even which customers show the highest returns to see if there is any correlation.

This dashboard has six components: map showing average returns by state, scatterplot of returns to sales, average calculated number of returns by customers, average number of returns by state, average number of returns by product, and another chart showing customer s with high returns and how much purchases they have made. The map was made to show if there is a correlation of whether the geographic locations or the type of product had on returns. From the result, we find out there were various products that had many returns and therefore it did not matter if particular product category had an effect. We also find out that for the most part, geographic location did not matter either since most of the states appeared to have the same number of returns, with the exception of some western states with above average returns.

The two composite charts (profits vs returns from customers and returns by state) show that there is a trend that most of the returns happend during the summer time and that some customers with the highest returns also produces the highest profit for the company (example customer = Seth Vernon). This leaves with the fact that we need to do be cognizant of our competitors during summer time and ask our customers with high returns what is causing them to return many of our products back.

When I found out there were customers making a lot of returns, I thought they were possibly committing fraud, but after finding out they make more purchases than returns, I then concluded that was not the case.

Lastly, i pulled the chart showing products with most returns to realize if certain products may be defective and should be discontinued.

Summary of analysis returns

1. How returns can be measured depends on who the stakeholders are. Examples include, the quality control department may measure the number of product returns to evaluate the quality of the products. The finance team may measure the quantity of returns to find out if the company is making a loss or profit from items being sold.

2. The root causes of returns can be ..

Summary:From these analysis, I have concluded that regardless of the product, various items will have high returns. Western states (California, Oregon, Washington, and Utah have the highest returns). At first, I thought the customers with the highest returns were possible committing fraud, but after pulling some data, I found out that even customers with high returns still produce a lot of sales. My proposal is to ask the customers with the highest returns, what is making them return the items- is it due to the dissatisfaction of the item, finding better prices elsewhere,etc?
